REDUCING THE ENCODING TIME OF MOTION ESTIMATION IN HEVC USING PARALLEL PROGRAMMING

by

VASAVEE VIJAYARAGHAVAN

Presented to the Faculty of the Graduate School of The University of Texas at Arlington in Partial Fulfillment of the Requirements for the Degree of

MASTER OF SCIENCE IN ELECTRICAL ENGINEERING

THE UNIVERSITY OF TEXAS AT ARLINGTON

December 2015
Acknowledgements

First and foremost, I would like to thank Dr. K. R. Rao for guiding and mentoring me and for being a constant source of encouragement throughout my thesis. He has been a pillar of support throughout my Masters degree program and a great guide for my thesis research. I would like to thank Dr. Jonathan Bredow and Dr. Ioannis D. Schizas for serving on my committee.

My sincere thanks to Kreig Dubose, Jim R Blakley and Mike Downs from Intel Corporation who have been supportive technically and emotionally to say “Yes you will successfully complete your thesis with flying colors” and huge thanks to Sravanthi Kota Venkata for the immense knowledge and help delivered by her that aided towards successful completion of my thesis.

I would like to thank my friend Karthik Arunachalam for providing me with strong fundamentals on parallel programming and my MPL lab mates for providing valuable inputs throughout my research.

Last but never the least: I would like to thank my family and friends for being the biggest support during the course of my Masters and my thesis research and without whom I would not have been here today.

Abstract

REDUCING THE ENCODING TIME OF MOTION ESTIMATION IN HEVC USING PARALLEL PROGRAMMING

VASAVEE VIJAYARAGHAVAN, MS

The University of Texas at Arlington, 2015

Supervising Professor: K.R.Rao

High Efficiency Video Coding (HEVC) [10] is the current state-of-art video codec which is widely being adopted by lot of users. It has close to 50% reduction in encoding time compared to its predecessor, H.264 or AVC [37] (Advanced Video Coding) at the cost of increased complexity. Lot of research is going towards reducing the complexity of this codec, at the same time, maintaining the visual quality that it produces and maintaining the reduced encoding time from its predecessor.

As an effort to decrease the encoding time further, there can be several approaches. Parallel processing is taking a dominant role in many places, especially in Graphics Processing Unit (GPU) and multi-cored processor based applications. Because of the ability of the parallel programming to utilize the multiple cores efficiently at the same time, in place of serial programming, this has been used in many applications which demand quicker completion.

If areas that are parallelizable are identified in any codec [38] (HEVC in this case), the encoding time can be drastically reduced by writing an efficient algorithm.
In parallel programming, it is very important that the parallelized portion has the least amount of dependencies; otherwise it will lead to reverse effects of what is actually expected.

Thus, the success lies in identifying the region of the codec that contributes more towards encoding time and that has least dependencies, and optimizing that portion of the codec. In this thesis, thorough analysis is done to identify the hot spots in the codec implementation, HM16.7, of High Efficiency Video Coding (HEVC) developed by the JCTVC team. This hotspot analysis is implemented using Intel’s most powerful tool, Intel® vTune™ Amplifier. The results of this hotspot analysis will be functions and loops that use most of the CPU time. Once this is identified, the respective function is targeted to be optimized using Parallel programming with OpenMP. Iterative runs are carried out on the modified code to check whether the code has been reasonably optimized. The final optimized code is tested for encoding videos using metrics such as PSNR (Peak Signal to Noise Ratio), R-D plot (Rate Distortion) and computational complexity in terms of encoding time.

Through optimization of the HEVC HM16.7 encoder, there is an average reduction of ~24.7% to ~42.3% in encoding time with ~3.5 to 7% PSNR gain and ~1.6% to 4% bitrate increase.

Chapter 1

INTRODUCTION

1.1 Motivation

In today’s technological world, the demand for videos is increasing at a dramatic rate, as the number of electronic devices become more and as they become very easy to use. At the same time, bandwidth requirements are never a factor that would go down. It rather keeps exploding as the need for videos to be watched over the web keeps increasing. There has been development of different video codecs by different companies, each of them trying to optimize the codec over the previous version. The better the coding algorithm, lesser might be the requirement for bandwidth to transmit the video. This again depends on multiple factors. This efficiency of the codec should not come at the cost of video quality. Some factors that are taken into consideration while designing a video codec are:

- Encoding Time.
- Video Quality (Measured by using objective measurement metrics such as PSNR, SSIM, BDRATE etc).
- File size of the encoded video (More the file size, better will be the video quality.)

These factors directly influence:

- Bandwidth requirement over the network.
- Quality of video watched by the user.
- Storage capacity of any server that stores and transmits the encoded video.
- Storage capacity of device that records and stores the compressed video.
High Efficiency Video Coding (HEVC) [10] is the current state-of-art video codec which is widely being adopted by lot of users. It has close to 50% reduction in encoding time compared to its predecessor, H.264 or AVC [37] (Advanced Video Coding) at the cost of increased complexity. Lot of research is going towards reducing the complexity of this codec, at the same time, maintaining the visual quality that it produces and maintaining the reduced encoding time from its predecessor.

1.2 Background Work

As an effort to decrease the encoding time further, there can be several approaches. Parallel processing is taking a dominant role in many places, especially in Graphics Processing Unit (GPU) and multi-cored processor based applications. Because of the ability of the parallel programming to utilize the multiple cores efficiently at the same time, in place of serial programming, this has been used in many applications which demand quicker completion.

If areas that are parallelizable are identified in any codec [38] (HEVC in this case), the encoding time can be drastically reduced by writing an efficient algorithm.

In parallel programming, it is very important that the parallelized portion has the least amount of dependencies, otherwise it will lead to reverse effects of what is actually expected.

Thus, the success lies in identifying the region of the codec that contributes more towards encoding time and that has least dependencies, and optimizing that portion of the codec.

1.3 Thesis Outline

In this thesis, efforts have been made to identify the hotspots in the HEVC [10] code and the tools that have been used for this will be explained in detail in the chapters that
follow. Also, studies have been made to identify the region of the code (functions) which are most parallelizable with least dependencies. Hence, the function which is to be optimized is identified (Figure 1.3.1). Optimization is achieved by using parallel programming on CPU + GPU based systems, keeping the serial code running in the CPU while launching the parallel code on the GPU.

![Diagram](image.png)

Figure 1-1 Identifying the region to be optimized in any given codec

1.4 Organization of this thesis

The following chapters of the report is organized in the following manner:

The need for video coding and an introduction to the same is explained in CHAPTER 2, followed by a brief introduction to High Efficiency Video Coding in CHAPTER 3. Detailed explanation of how to identify the region of the code to be optimized is explained in CHAPTER 4. An introduction to motion estimation in HEVC is given in CHAPTER 5 followed by an introduction to Parallel Programming in CHAPTER 6. The rest of the CHAPTERs from 7 to 10 explain the algorithm adopted in this thesis, experimental conditions, results, metrics used for comparison of obtained results and future work ending with references.
Chapter 2
GROWING NEED FOR VIDEO CODECS

2.1 Where do we use videos?

Almost ubiquitous everywhere!!!

We record videos and photos in our mobile phones. Try to upload them in YouTube or Facebook or send them through Skype or Whatapp! Something which we do on a day to day basis. We never realize how much of Internet traffic this uploading and downloading of videos/images consume. This is just us, the consumers.

Providers take the top seat in consuming the internet traffic. Broadcasters have challenges henceforth, in delivering quality videos to all of their customers.

The number of mobile devices have exploded. Personal computers (PCs) have become less existent and laptops and tablets have become the most convenient devices to carry wherever we go.

The challenge lies in matching the network traffic and bandwidth requirements on par with the growing number of portable electronic devices. Let us take a look at Internet traffic – something that is most spoken among the media folks in the industry.
2.2 Top Providers that consume the most of Internet Traffic [2]

Figure 2-1 Top consumers of Internet traffic [2]

Figure 2-2 Top Internet Traffic produced by Corporations in 2014 [2]

Figure 2-3 Facebook’s video boom [1] – [5]

Figure 2-4 Bandwidth Explosion [1] – [5]

Figure 2-5 Mobile bandwidth requirements driven up by OTT streaming [1] - [5]
The amount of videos watched by users in different resolutions through different electronic devices is exploding every year. Studies are being conducted by several organizations, which focus on network traffic and bandwidth consumption.
Here is a chart from Sandvine, the broadband network company [1]:

![Change in Bandwidth per User since October 2013 by Sandvine [1]](image)

Figure 2-8 Change in Bandwidth per User since October 2013 by Sandvine [1]

How worse will this scenario get, if users/providers start using raw videos? Let us see some numbers on comparison between raw video file size and compressed video file size.

2.4 That is why we need Video Compression!!

Consider a digital video sequence having a picture resolution of 720x480 and a frame rate of 30 frames per second (FPS). If a picture is represented using the YUV color space with 8 bits per component or 3 bytes per pixel, size of each frame is 720x480x3 bytes.

The disk space required to store one second of video is 720x480x3x30 = 31.1 MB. A one hour video would thus require 112 GB.

With the number of devices inside household increasing, the bandwidth requirement is also increasing. In addition to these extremely high storage and bandwidth requirements, using uncompressed video will add significant cost to the hardware and systems that process digital video.

Digital video compression with the help of video codecs is thus necessary even with exponentially increasing bandwidth and storage capacities. Fortunately, digital video has
significant redundancies and eliminating or reducing those redundancies results in compression.

Video compression is typically achieved by exploiting

1. Spatial
2. Temporal
3. Statistical and psycho-visual redundancies

2.5 Introduction and Evolution of Video Coding Standards [6]

Every video coding standards adopt compression strategy to compress every video.

Table 2-1 Compression Strategies [19]

<table>
<thead>

<td>Inter prediction</td>
</tr>
</tbody>
</table>
2.5.1 Spatial Redundancy Removal

Figure 2-9 Spatial Redundancy Removal using Intra Prediction [19]

Figure 2-10 Spatial Redundancy Removal using block transforms [19]

2.5.2 Perceptual Redundancy Removal [19]

Human visual system is more sensitive to low frequency information. Perceptual redundancy removal makes use of this. Not all video data are equally significant from a perceptual point of view.
Quantization is a good tool for perceptual redundancy removal. Most significant bits (MSBs) are perceptually more important than least significant bits (LSBs). Co-efficient dropping (quantization with zero bits) example is shown in Figure 2-12:

2.5.3 Statistical Redundancy Removal [19]

Not all pixel values in an image (or in the transformed image) occur with equal probability. Entropy coding (eg. Variable length coding) can be used to represent more frequent
values using shorter codewords and less frequently used values with longer codewords.

Different entropy coding includes:

Huffman coding

Golomb code

Arithmetic code

Rice code

Tunstall code

\[ 1^{\text{st}} \text{ order Entropy} = -\sum_{i=1}^{N} p_i \log_2 p_i \]

\( p_i \) is the probability of occurrence of symbol \( i = 1,2,3,\ldots,N \)

Minimum theoretical bit rate at which a group of \( N \) symbols can be coded.

Figure 2-13 Statistical redundancy removal using entropy coding technique [19]
2.5.4 Temporal Redundancy Removal [19], [20]

Inter prediction is used in temporal redundancy removal. Frame difference can be coded using DCT and then can be quantized and entropy encoded.

Inter prediction is implemented using motion compensation. Each frame of a video is divided into blocks and motion estimation/compensation is applied. For each block, the relative motion between the current block and a matching block of the same size in the previous frame is found out. Motion vectors are transmitted for each block. This is shown in Figure 2-9:
2.6 Temporal Prediction and Picture Coding Types [19]

Intra Picture (I) – Picture is coded without reference to other pictures.

Inter Picture (P, B, b):

- Uni-directionally predicted (P) Picture – Picture is predicted from one prior coded picture
- Bi-directionally predicted (B, b) Picture – Picture is coded from one prior coded and one future coded pictures (b picture is not used as reference).
2.7 Summary of Key steps in video coding

Step 1: Intra and Inter prediction

![Intra and Inter Prediction Modes](image)

Figure 2-17 Intra and Inter prediction modes [19]

Step 2: Transform and Quantization of residual (prediction error)

![Transform and Quantization](image)

*Residual Figure from J.Apostolopoulos, "video Compression," MIT 6.344 Lecture, Spring 2004.

Step 3: Entropy coding on syntax elements (e.g., prediction modes, motion vectors, coefficients)

Step 4: In-loop filtering to reduce coding artifacts

2.8 Video Compression Standards [19]

Video compression standards ensure inter-operability between encoder and decoder. They usually support multiple use cases and applications by introducing different levels and profiles. Video coding standards specifies decoder mapping of bits to pixels. There has been close to ~2x improvement in compression from one standard to the next every decade.
Figure 2-19 Video processing loop [19]

Chapter 3
HIGH EFFICIENCY VIDEO CODING

3.1 HEVC Background and Development [25], [26], [27], [28]

The standard now known as High Efficiency Video Coding (HEVC) reflects the accumulated experience of about four decades of research and three decades of international standardization for digital video coding technology. Its development was a massive undertaking that dwarfed prior projects in terms of the sheer quantity of engineering effort devoted to its design and standardization. The result is now formally standardized as ITU-T Recommendation H.265 and ISO/IEC International Standard 23008-2 (MPEG-H part 2). The first version of HEVC was completed in January 2013 (with final approval and formal publication following a few months later—specifically, ITU-T formal publication was in June, and ISO/IEC formal publication was in November).

3.2 New features of HEVC [19]

- Recursive coding tree structure (64x64 -> 4x4)
- Advanced intra prediction(33 angular, DC, Planar)
- Greater flexibility in prediction modes and transform block sizes
- DCT based interpolation filter
- Advanced inter prediction and Signaling of modes and motion vectors
- Discrete Sine Transform (DST) for intra(4x4) luma blocks
- Deblocking filter
- Scanning
- Sample adaptive offset

3.3 Working of HEVC in brief

Source video, consisting of sequence of video frames, is encoded or compressed by a video encoder to create a compressed video bit stream. The compressed bit stream is stored or transmitted.

A video decoder decompressed the bit stream to create a sequence of decoded frames.

Steps carried out by video encoder:
Partitioning each picture into multiple units
Predicting each unit using inter or intra prediction, and subtracting the prediction from the unit

Transforming and quantizing the residual (Original picture unit – Prediction)

Entropy Encoding the transform output, prediction information, mode information and headers

Steps carried out by video decoder:

Entropy decoding and extracting the elements of the coded sequence

Rescaling and inverting the transform stage

Predicting each unit and adding the prediction to the output of inverse transform

Reconstructing a decoded video image

Figure 3-5 Video encoder in HEVC [19]

3.4 HEVC High Level Syntax [25], [32]

An HEVC bitstream consists of a sequence of data units called network abstraction layer (NAL) units. Some NAL units contain parameter sets that carry high-level information regarding the entire coded video sequence or a subset of the pictures within it. Other NAL units carry coded samples in the form of slices that belong to one of the various picture types that are defined in HEVC. Some picture types indicate that the picture can
be discarded without affecting the decodability of other pictures, and other picture types indicate positions in the bitstream where random access is possible.

The slices contain information on how decoded pictures are managed, both what previous pictures to keep and in which order they are to be output. Some NAL units contain optional supplementary enhancement information (SEI) that aids the decoding process or may assist in other ways, such as providing hints about how best to display the video. The syntax elements that describe the structure of the bitstream or provide information that applies to multiple pictures or to multiple coded block regions within a picture, such as the parameter sets, reference picture management syntax, and SEI messages, are known as the “high-level syntax” part of HEVC.

A considerable amount of attention has been devoted to the design of the high-level syntax in HEVC, in order to make it broadly applicable, flexible and robust to data losses, and generally highly capable of providing useful information to decoders and receiving systems.

The elements in high level syntax includes:

- NAL Units/Types
- Parameter sets
- Slice Segments/Slices
- Random access
- Reference picture sets

In general, all syntax elements above the slice segment data layer are called high-level syntax. These elements have:

- Access to packets.
- Settings of low level coding tools
- Random-access information
- Metadata

![Diagram of HEVC Encoding and Decoding](image)

Figure 3-6 Overview of HEVC Encoding and Decoding [25]

3.5 The NAL Unit Header and the HEVC Bitstream [25]

There are two classes of NAL units in HEVC—video coding layer (VCL) NAL units and non-VCL NAL units. Each VCL NAL unit carries one slice segment of coded picture data while the non-VCL NAL units contain control information that typically relates to multiple coded pictures. One coded picture, together with the non-VCL NAL units that are associated with the coded picture, is called an HEVC access unit. There is no requirement that an access unit must contain any non-VCL NAL units, and in some applications such as video conferencing, most access units do not contain non-VCL NAL units. However, since each access unit contains a coded picture, it must consist of one or more VCL NAL units—one for each slice (or slice segment) that the coded picture is partitioned into.
VCL NAL Unit Types [25]

Table 3-1 shows all 32 VCL NAL unit types and their NAL unit type values in the NAL unit header. All VCL NAL units of the same access unit must have the same value of NAL unit type and that value defines the type of the access unit and its coded picture. For example, when all VCL NAL units of an access unit have NAL unit type equal to 21, the access unit is called a CRA access unit and the coded picture is called a CRA picture.

There are three basic classes of pictures in HEVC: intra random access point (IRAP) pictures, leading pictures, and trailing pictures.

3.6 Parameter Sets

Parameter sets in HEVC are fundamentally similar to the parameter sets in H.264/AVC, and share the same basic design goals—namely bit rate efficiency, error resiliency, and providing systems layer interfaces. There is a hierarchy of parameter sets in HEVC, including the Sequence Parameter Set (SPS) and Picture Parameter Set (PPS) which are similar to their counterparts in AVC. Additionally, HEVC introduces a new type of parameter set called the Video Parameter Set (VPS). Each slice references a single active PPS, SPS and VPS to access information used for decoding the slice.

The PPS contains information which applies to all slices in a picture, and hence all slices in a picture must refer to the same PPS. The slices in different pictures are also allowed to refer to the same PPS. Similarly, the SPS contains information which applies to all pictures in the same coded video sequence.

The VPS contains information which applies to all layers within a coded video sequence, and is intended for use in the upcoming layered extensions of HEVC, which will enable scalable and multiview coding. While the PPS may differ for separate pictures, it is common for many or all pictures in a coded video sequence to refer to the same PPS. Reusing parameter sets is bit rate efficient because it avoids the necessity to send shared information multiple times. It is also loss robust because it allows parameter set content to be carried by some more reliable external communication link or to be repeated frequently within the bitstream to ensure that it will not get lost.

This ability to reuse the content of a picture parameter set in different pictures and to reuse the content of SPSs and VPSs in different CVSs is what primarily distinguishes the concept of a “parameter set” from the “picture header” and “sequence header” syntax used in older standards established prior to AVC.
3.7 Block Structures and Parallelism Features in HEVC [25], [24]

The High Efficiency Video Coding (HEVC) standard is designed along the successful principle of block-based hybrid video coding. Following this principle, a picture is first partitioned into blocks and then each block is predicted by using either intra-picture or inter-picture prediction. While the former prediction method uses only decoded samples within the same picture as a reference, the latter uses displaced blocks of already decoded pictures as a reference.

Since inter-picture prediction typically compensates for the motion of real-world objects between pictures of a video sequence, it is also referred to as motion-compensated prediction. While intra-picture prediction exploits the spatial redundancy between neighboring blocks inside a picture, motion-compensated prediction utilizes the large amount of temporal redundancy between pictures.

In either case, the resulting prediction error, which is formed by taking the difference between the original block and its prediction, is transmitted using transform coding, which exploits the spatial redundancy inside a block and consists of a decorrelating linear transform, scalar quantization of the transform coefficients and entropy coding of the resulting transform coefficient levels.
Figure 3-9 shows a block diagram of a block-based hybrid video encoder with some characteristic ingredients of HEVC regarding its novel block partitioning concept.

![Block diagram of an HEVC encoder with built-in decoder (gray shaded)](image)

Figure 3-9 Block diagram of an HEVC encoder with built-in decoder (gray shaded)

Figure 3-10 HEVC Encoder with lossless encoding mode [24]

This innovative feature of HEVC along with its specific key elements will be one of the main subjects of this chapter. In a first step of this new block partitioning approach, each picture in HEVC is subdivided into disjunct square blocks of the same size, each of which serves as the root of a first block partitioning
quadtree structure, the coding tree, and which are therefore referred to as coding tree blocks (CTBs). The CTBs can be further subdivided along the coding tree structure into coding blocks (CBs), which are the entities for which an encoder has to decide between intra-picture and motion-compensated prediction.

Parallel picture processing is achieved using:

Slices/Slice segments

- Tiles
- Wavefront Parallel Processing (WPP)

3.8 Picture Partitioning [19], [25]

3.8.1 Coding tree unit:

HEVC has replaced the concept of macro blocks (MBs) with coding tree units. The coding tree unit has a size selected by the encoder and can be larger than the traditional macro blocks. It consists of luma coding tree blocks (CTB) and chroma CTBs. HEVC supports a partitioning of the CTBs into smaller blocks using a tree structure and quad tree-like signaling [10][14].

The quad tree syntax of the CTU specifies the size and positions of its luma and chroma coding blocks (CBs). One luma CB and ordinarily two chroma CBs, together with associated syntax, form a coding unit (CU) for 4:2:0 format.
Each CU has an associated partitioning into prediction units (PUs) and a tree of transform units (TUs). Similarly, each CB is split into prediction blocks (PB) and transform blocks (TB) [15]. The decision whether to code a picture area using inter-picture or intra-picture prediction is made at the CU level. Figure 3-12 shows different sizes of a CTU [17].
Figure 3-12 Different sizes of CTU [17]

Figure 3-13 Sub-division of a CTB into TBs and PBs [8].
Larger CTU sizes typically enable better compression.

HEVC then supports a partitioning of the CTBs into smaller blocks using a tree structure and quad tree-like signaling.
3.9 Transform Units [33], [34]

Similar with the PU, one or more TUs are specified for the CU.

HEVC allows a residual block to be split into multiple units recursively to form another quad tree which is analogous to the coding tree for the CU [12].

The TU is a basic representative block having residual for applying the integer transform and quantization.

For each TU, one integer transform having the same size as the TU is applied to obtain residual transform coefficients.

![Figure 3-16 Examples of transform tree and block partitioning [33]](image-url)
Figure 3-17 Block partitioning comparison between HEVC and H.264 [19]

Figure 3-18 Smart picture partition in HEVC compared to H.264 [8]
3.10 Encoder Features:

3.10.1 Motion vector signaling:

The HEVC standard uses a technique called advanced motion vector prediction (AMVP) to derive several most probable candidates based on data from adjacent PBs and the reference picture. A “merge” mode for MV coding can be also used, allowing the inheritance of MVs from neighboring PBs [10]. Moreover, compared to H.264/MPEG-4 AVC, improved “skipped” and “direct” motion inference are also specified [10].

3.10.2 Motion compensation:

The HEVC standard uses quarter-sample precision for the MVs, and for interpolation of fractional-sample positions it uses 7-tap (filter co-efficients: -1, 4, -10, 58, 17, -5, 1) or 8-tap filters (filter co-efficients: -1, 4, -11, 40, 40, -11, 4, 1). In H.264/MPEG-4 AVC there is 6-tap filtering (filter co-efficients: 2, -10, 40, 40, -10, 2) of half-sample positions followed by a bi-linear interpolation of quarter-sample positions [10]. Each PB can transmit one or two motion vectors, resulting either in uni-predictive or bi-predictive coding, respectively [10]. As in H.264/MPEG-4 AVC, a scaling and offset operation may be applied to the prediction signals in a manner known as weighted prediction [10].

38
Motion Compensation consists of three steps:

1. Fetch - reference data, padding is applied if reference block outside picture boundaries.
2. Interpolation – for fractional motion vectors (MV)
3. Weighted Prediction

3.11 Intra-picture prediction:

Intra prediction in HEVC is quite similar to H.264/AVC [15]. Samples are predicted from reconstructed samples of neighboring blocks. The mode categories remain identical: DC, plane, horizontal/vertical, and directional; although the nomenclature for H.264’s plane
and directional modes has changed to planar and angular modes, respectively [15]. For intra prediction, previously decoded boundary samples from adjacent PUs must be used. Directional intra prediction is applied in HEVC, which supports 17 modes for 4x4 block and 34 modes for larger blocks, inclusive of DC mode [18]. Directional intra prediction is based on the assumption that the texture in a region is directional, which means the pixel values will be smooth along a specific direction [18].

The increased number of directions improves the accuracy of intra prediction. However it increases the complexity and increased overhead to signal the mode [18]. With the flexible structure of the HEVC standard, more accurate prediction, and other coding tools, a significant improvement in coding efficiency is achieved over H.264/AVC [18]. HEVC supports various intra coding methods referred to as Intra_Angular, Intra_Planar and Intra_DC. In [16], an evaluation of HEVC coding efficiency compared with H.264/AVC is provided. It shows that the average bit rate saving for random access high efficiency (RA HE) case is 39%, while for all intra high efficiency (Intra HE) case this bit rate saving is 25%, which is also considerable. It seems that further improvement of intra coding efficiency is still desirable. Figure 3.6.2.3.1 shows different intra prediction modes for HEVC [18].
3.12 Quantization control:

As in H.264/MPEG-4 AVC, uniform reconstruction quantization (URQ) is used in HEVC, with quantization scaling matrices supported for the various transform block sizes [10]. These metrics reflect the HVS.

3.13 Entropy Coding:

HEVC uses context adaptive binary arithmetic coding (CABAC) for entropy coding which is similar to the one used in H.264/MPEG-4 AVC. It has some changes to improve its throughput speed. These improvements can be used for parallel processing architectures and its compression performance, and to reduce its context memory requirements.

4.6 In-loop deblocking filter:

The HEVC standard uses a deblocking filter in the inter-picture prediction loop as used in H.264/MPEG-4 AVC. But design has been simplified in regard to its decision-making and filtering processes, and is made more friendly to parallel processing [10].
A non-linear amplitude mapping is introduced in the inter-picture prediction loop after the deblocking filter. The goal is to better reconstruct the original signal amplitudes by using a look up table that is described by a few additional parameters that can be determined by histogram analysis at the encoder side [10].

3.15 HEVC Extensions and Emerging Applications [46]:

Range Extensions (Finalized in April 2014)
- Support for 4:2:2, 4:4:4 color sample video, 12-bit Video

Scalable Video Coding (Finalized in July 2014) (HSVC)
- Supports layered coding -spatial, quality, color gamut scalability

Multiview Video Coding (Finalized in July 2014) (MVC)
- Supports coding of multiple views, 3D stereoscopic video

Screen Content Coding (Expected to be finalized Feb. 2016) (SCC)
- Coding mixed contents consisting of natural video, text / graphics etc.

High dynamic range (HDR) / wide color gamut (WCG)

Post-HEVC activity (VCEG and MPEG AHG work)
Chapter 4
MOTION ESTIMATION IN HEVC

The use of GPUs in video processing and the suitability of the regions of HEVC code in parallel processing is briefed in this chapter. [38]

Figure 4-1 Why GPUs?
HEVC Decoding on Capable GPUs

GPUs are **massively multithreaded** devices capable of handling hundreds or thousands of threads in parallel at any given time.

Only highly **data parallel** algorithms of video codec can be efficiently offloaded to the GPU for processing.

- Motion Compensation
- Intra Prediction
- Recon
- Deblocking & SAO
- Parsing & Entropy Decode
- Inverse Quant
- Inverse Transform

*Not suitable for GPU execution*  *Data parallel execution, suitable for GPU execution*

**Figure 4-2 Decoding capability of GPUs**

Motion Compensation

The current picture/frame pixels is predicted from the reference frame's pixels.

- The reference picture can be from past or future
- The prediction happens on a block-by-block basis
- And there can be multiple reference frames for each block

**Figure 4-3 Motion Compensation in HEVC**
Figure 4-4 Most compute intensive region of Motion Compensation
Chapter 5
PARALLEL COMPUTING USING OPENMP [87]

Parallel computing allows simultaneous execution of threads – not same thing as concurrent execution. Computer Architectures can be classified in two different dimensions, the number of instruction streams that can be processed at any given time, and the number of data streams that can be processed at any given time.

![Comparison of different architectures](image)

Figure 5-1 Comparison of different architectures

5.1 Parallel Computing in Microprocessors
Some have thought Moore’s law was a predictor of clock speeds, 0.1 MHz – 3.3 GHz.

- Instruction Level Parallelization (ILP) – Out of Order Processing – Hardware Level
- Multiple processes or threads – Software level
5.2 Threads

- A Thread is a discrete sequence of related instructions that is executed independently of other instruction sequences.
- Hardware Level Definition: A thread is an execution path that remains independent of other hardware execution paths.
- OS maps software threads to hardware execution
- Thread only needs the architecture state – registers, execution units, etc.
- Logical Processor can be created by duplicating the architecture space.

5.3 What Are Threads Good For?

- Making programs easier to understand
- Overlapping computation and I/O
- Improving responsiveness of GUIs
- Improving performance through parallel execution

5.4 Thread Concurrency vs. Parallelism

![Concurrency vs Parallelism Diagram]

Figure 5-2 Concurrency versus parallelism
5.5 Thread Level Parallelism

• Time-sliced multi-threading – single processor
• Multiple processors – multiple threads or processes run simultaneously on multiple processors
• Physical processor – includes many resources including architecture state (registers, caches, execution units, etc.)

5.6 Hyper-Threading

• Simultaneous multi-threading or SMT - The actual Execution units shared by the different logical processors.
• Intel’s implementation called Hyper-threading or HT
• To the OS (e.g., Windows) the computing unit appears as multiple physical processors and threads scheduled accordingly.

• In the Flynn Taxonomy, a superscalar processor is classified as a MIMD processor (Multiple Instructions, Multiple Data)

5.7 Speedup Example

Examples: Speedup half the program by 15% using parallel processing, then

\[ \text{Speedup} = \frac{1}{(1-0.5) + (0.5/1.15)} = \frac{1}{0.5+0.43} = 1.08 \]

Thus whole program speedup by 8 percent.

5.8 Speed Up

Expressing in terms of the serial and parallel portions:

\[ \text{Speedup} = \frac{1}{S + (1-S)/n} \]

Where S is the time spent executing the serial portion of program and n is the number of execution cores

If n = 1, then there is no speedup

As n = increases without bound,
5.9 Parallel Code vs. Parallel Processors

• For 2 cores and a 30% parallelized program
  \[ \frac{1}{0.7 + 0.3/2} = 1.176 \text{ or } S = 17.6 \text{ percent} \]
  \[ \frac{1}{0.7 + 0.3/4} = 1.29 \text{ or } 29 \text{ percent} \]
  \[ \frac{1}{0.4 + 0.6/2} = 1.818 = 82 \% \]

• Thus only when the program is mostly parallelized does adding more processors help the most

Typical Stack Representation for Multithreaded Process

![Stack representation of Multithreaded process](image)

Figure 5-3 Stack representation of Multithreaded process

5.10 More General Threads Model

• When program begins execution, only one user thread, called the main thread, is active

• The main thread can create other threads, which execute other functions

• Created threads can also create additional threads
• How this is done varies according to programming language or API

Operating States of a Thread

Figure 5-4 Operating states of a thread

5.11 Application Threads

Application threads can be implemented at the application level using established API’s such as OpenMP, Pthreads, Windows threads - Win32/MFC, Intel Threads, etc. Examine the OpenMP Program:

```c
#include <stdio.h>
#include <omp.h>
int main()
{
  int threadID, totalThreads;
  /* OpenMP pragma specifies that following block is
going to be parallel and the threadID variable is
private in this openmp block. */
```
```c
#pragma omp parallel private(threadID)
{
    threadID = omp_get_thread_num();
    printf("Hello World is from thread %d\n", (int)threadID);
    /* Master thread has threadID = 0 */
    if (threadID == 0) {
        printf("Master thread being called\n");
        totalThreads = omp_get_num_threads();
        printf("Total number of threads are %d\n", totalThreads);
    }
}
return 0;
}
```

Each Thread Executes The Same Code Unless Directed by IF Statement

Figure 5-5 Sample openMP program
Example - Find the Number of Processors

Function `omp_get_num_procs` returns the number of physical processors available to the parallel program

```c
int omp_get_num_procs (void);
```

Example:

```c
int t;
...
```
```
t = omp_get_num_procs();
```

Get Number of Threads Currently in Use

- `omp_get_thread_num();`
- Returns the number of threads currently in use

Setting the Number of Threads

- Function `omp_set_num_threads` allows you to set the number of threads that should be active in parallel sections of code
  ```c
  void omp_set_num_threads (int t);
  ```
- The function can be called with different arguments at different points in the program
  ```c
  int t;
  ...
  ```
  ```c
  omp_set_num_threads (t);
  ```
5.12 Reductions

- Given associative binary operator \( \oplus \) the expression

\[
a_1 \oplus a_2 \oplus a_3 \oplus \ldots \oplus a_n
\]

is called a reduction

- The ‘value’-finding program performs a sum-reduction without specifying a critical section.

    double area, pi, x;
    int i, n;

    ... 
    area = 0.0;

    #pragma omp parallel for private(x) reduction(+:area)
    for (i = 0; i < n; i++) {
        x = (i + 0.5)/n;
        area += 4.0/(1.0 + x*x);
    }
    pi = area / n;

5.13 OpenMP reduction Clause

- OpenMP provides a reduction clause for the parallel for pragma

- Reduction Eliminates need for:

    Creating private variable

    Dividing computation into accumulation of local answers that contribute to global result
5.14 Ways of Exploiting Parallelism

• Data decomposition (Domain)
• Task (functional) decomposition
• Pipelining (Data Flow)

5.15 Different Forms of Decomposition

• Task - Different activities assigned to different threads
• Data – Multiple threads performing the same operation but on different blocks of data
• Data Flow – One thread’s output is the input to a second thread

5.16 Parallel Programming Patterns

• Task-level parallelism - Task
  In this pattern, the problem is decomposed into a set of tasks that operate independently. It is often necessary remove dependencies between tasks or separate dependencies using replication.

• Divide and Conquer - Task/Data
  The problem is divided into a number of parallel sub-problems. Each sub-problem is solved independently.

• Geometric Decomposition - Data
  The geometric decomposition pattern is based on the parallelization of the data structures.

• Pipeline - Data Flow
  Identical to that of an assembly line. - break down the computation into a series of stages and have each thread work on a different stage simultaneously.

• Wavefront - Data Flow
  The wavefront pattern is useful when processing data elements along a diagonal in a two-dimensional grid.
Chapter 6
IMPLEMENTATION

6.1 Analysis and algorithm implementation

JCTVC has provided an open source implementation of the state-of-art video codec, HEVC [74]. The idea behind this thesis can be organized as modules as follows:

6.1.1 Module 1: Analysis of the basic HM software (HM 16.7 is used in this thesis)

Steps:

1. Download the HM16.7 (or any latest version of HM) from the website link given in [74].
2. Build the convenient version in Visual studio. This will generate a .exe file in the bin folder of the HM source.
3. Open the Intel® vTune™ amplifier->Create New Project->Add the link to the executable->Run basic Hotspot analysis.
4. Parameters to be given to the application while running hotspot analysis should be the same as command line parameters that will be given to actually encode the video sequence: 
   -c <path_to_cfg/sample.cfg> -i <path_to_input/input.y4m> -wdt <width_of_input> -hgt <height_of_input> -f <number_of_frames_to_be_encoded> -fr <frame_rate>
5. The results of running the vTune analysis will be the top 5 Hotspots that consume most of the CPU time while running the application.
6. Click on each of these Hotspots to view the exact functions in the code in which they come from.
7. Modify that particular region of the code and re-run the analysis from step 1 to 5.
8. Notice the improvement in the total CPU time.
9. The top hotspots should disappear if the functions are well optimized.

Video sequences have been chosen based on:

1. Complexity or the amount of movement in the video (Easy, Medium, Hard).
2. Resolution (Since HEVC is meant for encoding high resolution streams, 1080p and 2060p were decided to be used for analysis. But 2060p videos took 6 hours to encode even on the most powerful Intel hardware since the HM code is not well optimized)

Table 6-1 Video Sequences used in Intel® vTune™ amplifier analysis

<table>

</tr>
</tbody>
</table>

Note: All these sequences are downloaded from link given in reference [85]

6.1.2 Module 2: Change the configuration parameters of the HM software

HEVC software provides a wide range of parameters as specified in the HM software manual [74]. Playing around with these parameters will save a lot of encoding time at reasonable/no loss of quality.

In this module, different parameters are changed, the encoding is carried out to see the results and the final best parameter settings for the HM encoder are chosen.
6.1.3 Module 3: vTune analysis of modified code to find parallelizable loops

vTune is a very powerful tool which has the best capabilities of analysis of the code in every aspect. vTune lets us see the loops in the code which take a lot of time of the encoder.

These loops are spotted using the “Functions and Loops” option in the Bottom Up pane of the results from analysis. These loops are checked for parallelism by using Open MP. A detailed and repetitive analysis of the HM code for parallel loops revealed that the code is not well suited for parallelism, since parallelizing degraded the performance badly.

There are lots of loops in the code which have already been optimized using vectorization. Memory misaligned functions/loops were also spotted and analyzed that proper memory alignment of these will lead to less cache misses and hence improved performance at the microprocessor architecture level.

6.1.4 Module 4: Performance comparison of Original and Optimized HM encoders

Finally after all the analysis until module 3, the .exe files from both original and optimized code are run for the following setting:
Table 6-2 Encoder Comparison Configurations used in this thesis

</table>

6.2 Metrics used for comparison:

Each of the 72 iterations will be evaluated for the following metrics:

1. PSNR
2. Encoding Time
3. RD-plot

6.3 Experimental Setup

The following include the configuration and requirements for carrying out the thesis:

6.3.1 System:

CPU: Intel® Core™ i7-4770R CPU @ 3.20GHz

GPU: Intel® Iris™ Pro Graphics 5200
6.3.2 Software:
HM16.7 reference software

6.3.3 Tools/IDEs:
Microsoft Visual Studio
Intel ® vTune ™ amplifier
Matlab

6.3.4 Test Sequences:
Crowd Run
Park Joy
Ducks Take off
Chapter 7
Measurement Methods and Results

7.1 Measurement Quality Metrics Used for Comparison

**BD-rate and BD-PSNR** [47]

The program below computes the Bjontegaard metric to measure the average difference between two rate-distortion curves:

```matlab
function avg_diff = bjontegaard(R1,PSNR1,R2,PSNR2,mode)
% BJONTEGAARD    Bjontegaard metric calculation
% Bjontegaard's metric allows to compute the average gain in PSNR or the average per cent saving in bitrate between two rate-distortion curves [1].
% Differently from the avsnr software package or VCEG Excel [2] plugin this tool enables Bjontegaard's metric computation also with more than 4 RD points.
% R1,PSNR1 - RD points for curve 1
% R2,PSNR2 - RD points for curve 2
% mode -
% 'dsnr' - average PSNR difference
% 'rate' - percentage of bitrate saving between data set 1 and data set 2
% avg_diff - the calculated Bjontegaard metric ('dsnr' or 'rate')
```
\% (c) 2010 Giuseppe Valenzise
\%

\[ \text{min\_int} = \text{min}([\text{PSNR1}; \text{PSNR2}]); \]
\[ \text{max\_int} = \text{max}([\text{PSNR1}; \text{PSNR2}]); \]

% find integral
\[ p_{\text{int1}} = \text{polyint}(p1); \]
\[ p_{\text{int2}} = \text{polyint}(p2); \]

\[ \text{int1} = \text{polyval}(p_{\text{int1}}, \text{max\_int}) - \text{polyval}(p_{\text{int1}}, \text{min\_int}); \]
\[ \text{int2} = \text{polyval}(p_{\text{int2}}, \text{max\_int}) - \text{polyval}(p_{\text{int2}}, \text{min\_int}); \]

% find avg diff
\[
\text{avg\_exp\_diff} = \frac{\text{int2}-\text{int1}}{\text{max\_int}-\text{min\_int}};
\]
\[
\text{avg\_diff} = (\exp(\text{avg\_exp\_diff})-1) \times 100;
\]
end

Mean Squared Error (MSE) and Peak Signal to Noise Ratio (PSNR)

The term peak signal-to-noise ratio (PSNR) is an expression for the ratio between the maximum possible value (power) of a signal and the power of distorting noise that affects the quality of its representation. Because many signals have a very wide dynamic range, (ratio between the largest and smallest possible values of a changeable quantity) the PSNR is usually expressed in terms of the logarithmic decibel scale.

Image enhancement or improving the visual quality of a digital image can be subjective. Saying that one method provides a better quality image could vary from person to person. For this reason, it is necessary to establish quantitative/empirical measures to compare the effects of image enhancement algorithms on image quality.

Using the same set of tests images, different image enhancement algorithms can be compared systematically to identify whether a particular algorithm produces better results. The metric under investigation is the peak-signal-to-noise ratio. If we can show that an algorithm or set of algorithms can enhance a degraded known image to more closely resemble the original, then we can more accurately conclude that it is a better algorithm.

For the following implementation, let us assume we are dealing with a standard 2D array of data or matrix. The dimensions of the correct image matrix and the dimensions of the degraded image matrix must be identical.

The mathematical representation of the PSNR is as follows:
$PSNR = 20 \log_{10} \left( \frac{MAX_f}{\sqrt{MSE}} \right)$

Figure 7-1 Peak Signal-to-Noise Equation

where the MSE (Mean Squared Error) is:

$$MSE = \frac{1}{mn} \sum_{0}^{m-1} \sum_{0}^{n-1} ||f(i,j) - g(i,j)||^2$$

Figure 7-2 Mean Squared Error Equation

This can also be represented in a text based format as:

MSE = (1/(m*n))*sum(sum((f-g).^2))

PSNR = 20*log(max(max(f)))/((MSE)^0.5)

Legend:

f represents the matrix data of our original image

g represents the matrix data of our degraded image in question

m represents the numbers of rows of pixels of the images and i represents the index of that row

n represents the number of columns of pixels of the image and j represents the index of that column

MAXf is the maximum signal value that exists in our original "known to be good" image

The mean squared error (MSE) for our practical purposes allows us to compare the “true” pixel values of our original image to our degraded image. The MSE represents the average of the squares of the “errors” between our actual image and our noisy image.
The error is the amount by which the values of the original image differ from the degraded image.

The proposal is that the higher the PSNR, the better degraded image has been reconstructed to match the original image and the better the reconstructive algorithm. This would occur because we wish to minimize the MSE between images with respect the maximum signal value of the image.

When you try to compute the MSE between two identical images, the value will be zero and hence the PSNR will be undefined (division by zero). The main limitation of this metric is that it relies strictly on numeric comparison and does not actually take into account any level of biological factors of the human vision system such as the structural similarity index. (SSIM)

For color images, the MSE is taken over all pixels values of each individual channel and is averaged with the number of color channels. Another option may be to simply perform the PSNR over a converted luminance or grayscale channel as the eye is generally four times more susceptible to luminance changes as opposed to changes in chrominance. This approximation is left up to the experimenter.

7.2 Results
7.2.1 Initial vTune analysis

Settings: HM16.7 code analysed in vTune for DucksTakeOff, CrowdRun and ParkJoy.y4m sequences. Visual Studio is used to build the code in debug mode (before and after optimization) by enabling the settings:
C/C++->Optimization->Inline Functions->No Debugging->Yes
Figure 7-3 Disable Inline function in Visual Studio project property

Figure 7-4 Enable debugging in project properties in Visual Studio
Project->Properties->x64 (my hardware’s configuration-best suited for vTune analysis)

![Configuration Settings](image)

Figure 7-5 Set the configuration to 64 bit in Visual studio project properties

After setting these options, build the HM16.7 project in VS201x.

Steps to run vTune analysis shown below:

Create New Project in vtune amplifier as shown below:

![Create Project](image)

Figure 7-6 Create a new project in Intel® vTune™ Amplifier
Click on Basic Hotspot analysis:

Figure 7-7 Begin a basic hotspot analysis

Click on Project Properties and edit as per requirement:

Figure 7-8 Modify the project properties
Enter the application parameters as shown below:

![Application parameters example](image)

**Figure 7-9 Type in the application name and application parameters**

Sample application parameters: `-c`  
`C:\\Users\\vvijayar\\Documents\\Vasavee_Official\\Thesis\\HMOptimizedV1\\encoder_intra\\main.cfg` `-i ducks_take_off_1080p50.y4m` `-hgt 1920` `-wdt 1080` `-f 10` `-fr 30`

Click on Start to start the hotspot analysis:

#============ Tiles ================
TileUniformSpacing : 0  # 0: the column boundaries are indicated by TileColumnWidth array, the row boundaries are indicated by TileRowHeight array
# 1: the column and row boundaries are distributed uniformly
NumTileColumnsMinus1 : 0  # Number of tile columns in a picture minus 1
TileColumnWidthArray : 2 3  # Array containing tile column width values in units of CTU (from left to right in picture)
NumTileRowsMinus1 : 0  # Number of tile rows in a picture minus 1
TileRowHeightArray : 2  # Array containing tile row height values in units of CTU (from top to bottom in picture)

LFCrossTileBoundaryFlag : 1  # In-loop filtering is across or not across tile boundary.
# 0: not across, 1: across

#============ WaveFront ================
WaveFrontSynchro : 0  # 0: No WaveFront synchronisation
(WaveFrontSubstreams must be 1 in this case).
# >0: WaveFront synchronises with the LCU above and to the right by this many LCUs.
Final Encoder Performance Comparison between Original and Optimized code after Parallelization using OpenMP

Encoder versions: HM16.7_Original.exe and HM16.7_Modified.exe

Configuration Files: encoder_intra_main.cfg

VideoSequences: DucksTakeOff_1080p.y4m, CrowdRun_1080p.y4m, ParkJoy_1080p.y4m, DucksTakeOff_720p.y4m, CrowdRun_720p.y4m, ParkJoy_720p.y4m

Quantization Parameters: 22, 24, 26, 28, 30, 32

Metrics Generated by encoder: Encoding time and PSNR
Metrics Generated from Matlab: BD-rate and BD-PSNR

The following PSNR, Encoding time and RD plots are described for 6 different Quantization Parameters (QPs) – 22,24,26,28,30,32 and for two different resolutions (1080p and 720p) for three different sequences (DucksTakeOff (easy), ParkJoy(medium) and CrowdRun(heavy)) classified in terms of motion in each of the video. These are chosen keeping in mind that HEVC is designed for high resolution videos and that the optimized encoder is tested for low to high quality and low to high complexity.

Figure 7-48 ParkJoy (1920x1080 and 1280x720)
7.2.4 PSNR comparison plots between un-optimized and optimized versions of HM16.7 (HEVC):

Figure 7-49 PSNR comparison plot for CrowdRun_1080p.y4m

Figure 7-50 PSNR comparison plot for CrowdRun_720p.y4m
Figure 7-51: PSNR comparison plot for DucksTakeOff_1080p.y4m

Figure 7-52 PSNR comparison plot for DucksTakeOff_720p.y4m
Figure 7-53 PSNR comparison plot for ParkJoy_1080p.y4m

Figure 7-54 PSNR comparison plot for ParkJoy_720p.y4m
Figures 8-2 to 8-7 illustrate the difference in PSNR between the original HM software encoder and the optimized HM software encoder. These plots show that the optimized software has a slight increase in PSNR for every QP and for each of the three sequences, thus ensuring that the quality of the video is not degraded.

7.2.5 Encoding Time comparison plots between un-optimized and optimized versions of HM16.7 (HEVC):

![Encoding Time Comparison Chart](image)

Figure 7-55 Encoding Time Comparison plot for CrowdRun_1080p.y4m
Figure 7-56 Encoding Time Comparison plot for CrowdRun_720p.y4m

Figure 7-57 Encoding Time Comparison plot for DucksTakeOff_1080p.y4m
Figure 7-58 Encoding Time Comparison plot for DucksTakeOff_720p.y4m

Figure 7-59 Encoding Time Comparison plot for ParkJoy_1080p.y4m
Figures 8-8 to 8-13 show the difference in Encoding time between the original HM software encoder and the optimized HM software encoder. It can be observed from these plots that the purpose of this thesis is successfully accomplished i.e., reduction in encoding time with no loss of quality using parallel programming with OpenMP.
7.2.6 RD-plot comparison plots between un-optimized and optimized versions of HM16.7 (HEVC):

**Figure 7-61 RD-plot comparison for CrowdRun_1080p.y4m**

**Figure 7-62 RD-plot comparison for CrowdRun_720p.y4m**
Figure 7-63 RD-plot comparison for DuckstakeOff_1080p.y4m

Figure 7-64 RD-plot comparison for DuckstakeOff_720p.y4m
Figure 7-65 RD-plot comparison for ParkJoy_1080p.y4m

Figure 7-66 RD-plot comparison for ParkJoy_720p.y4m
Figures 8-14 to 8-19 show the RD plot comparison between the original and optimized HM encoders. It is very evident from these plots that a slight bitrate increase has been encountered with the optimized software with no loss of quality (PSNR).
Chapter 8
CONCLUSIONS AND FUTURE WORK

8.1 Conclusions

Through thorough analysis with the most powerful tool, Intel® vTune™ amplifier, hotspots were identified in the HM16.7 encoder. These hotspots are the most time consuming functions/loops in the encoder. The functions are optimized using optimal C++ coding techniques and the loops that do not pose dependencies are parallelized using the OpenMP directives available by default in Windows Visual Studio.

Not every loop is parallelizable. Thorough efforts are needed to understand the functionality of the loop to identify dependencies and the capability of the loop to be made parallel. Overall observation is that the HM code is already vectorized in many regions and hence parallel programming on top of vectorization may lead to degradation in performance in many cases. Thus the results of this thesis can be summarized as below:

- Overall ~24.7 to 42.3% savings in encoding time.
- Overall ~3.5 to 7% gain in PSNR.
- Overall ~1.6 to 4% increase in bitrate.

Though this research has been carried out on a specific configuration (4 core architecture), it can be used on any hardware universally. This implementation works on servers and Personal Computers. Parallelization in this thesis has been done at the frame level.
Figure 8-1 Summary of Results
OpenMP framework is a very simple yet easy to adapt framework that aids in thread level parallelism. Powerful parallel programming APIs are available which can be used in offloading the serial code to the GPU. Careful efforts need to be invested in investigating the right choice of software and functions in the software chosen to be optimized. If optimized appropriately, huge savings in encoding time can be achieved.

Intel® vTune™ amplifier is a very powerful tool which makes it possible for analysis of different types to be carried at the code level as well as at the hardware level. The analysis that has been made use of in this thesis is Basic Hotspot analysis. There are other options available in the tool, one of which helps us to identify the regions of the code which cause the maximum number of locks and waits and also the number of cache misses that occur. Microprocessor and assembly level optimization of the code base can be achieved by diving deep into this powerful tool.

Biographical Information

Vasavee Vijayaraghavan was born in Chennai, Tamil Nadu, India. After completing her schooling at school in Chennai in 2007, she went on to obtain her B.E in Electrical and Electronics Engineering from MNM Jain Engineering College from 2007 - 2011. From 2011 to 2013, she worked as a Systems Engineer with Infosys Technologies, Chennai.

She joined University of Texas at Arlington to pursue her M.S in Electrical Engineering in 2013. This was around the time she joined the Multimedia Processing Lab. She is presently working as a Summer/Fall Graduate Engineer intern at Intel Corporation, Oregon and subsequently will join the same team after she graduates.
